Electron Phonon Interaction In Low

Abstract Recent theoretical studies have shown that charge transport in high-mobility organic semiconductors is limited by low-frequency vibrations because of strong non-local electron-phonon interaction.

The important role of a temperature dependent many-body effect due to electron-phonon interactions and spin fluctuations at low T has been seen in Lu and Sc (Swenson 1996). At high temperatures ($T > \sim \theta_D / 2$) a description of β_{el} in terms of $N(E_F)$ is sufficient, but then the total expansion coefficient is dominated by the phonon part β_{ph} .

Low temperature magnetoresistance measurements in GaAs-GaAlAs heterojunctions with more than one occupied electric subband. Shubnikov-de Haas oscillations in perpendicular magnetic fields contain non-additive terms at electron temperatures $> 2K$, where acoustic phonon mediated inter-subband scattering is comparable to intra-subband scattering.

Electron-phonon and phonon-phonon interactions in low-dimensional nanostructures. Lanzillo, Nicholas Anthony. Abstract. The electron-phonon interaction gives rise to a number of physically measurable quantities in solid state physics, perhaps most notably the heat capacity and the finite electrical resistivity in metals.

The low temperature electron-phonon interaction is also an elementary process for several other phenomena and applications. The electron-phonon interaction determines the cooling time of the electron gas, if the electrons are not cooled by out diffusion (see Chapter 2).

Abstract We present a GaN-based quantum-cascade device whose inter-subband emission shows strong electron-phonon interaction. To generate the luminescence, an external electrical field – which partially screened the internal polarization – had to be applied. In low intensity spectra, a pattern of secondary peaks occurs.

Phonon interactions in solid-state photonics systems cause intrinsic quantum decoherence and often present the limiting factor in emerging quantum technology. Due to recent developments in nanophotonics, exciton-cavity structures with very strong light-matter coupling rates can be fabricated. We show that in such structures, a new regime emerges, where the decoherence is completely suppressed ...
